Bona fide Certificate

This project work on

“Travallae”

is the bona fide work of

“

Prabin KC (037503-24),

Subodh Baniya (037478-24),

Aashutosh Karki (037505-24),

Prayash Bhattarai (037485-24)

”

who carried out the project work under my supervision.

Project Supervisor

Dr. Pankaj Raj Dawadi

Associate Professor

Department of Computer Science and Engineering

Acknowledgements

To everyone who contributed to the success of our project, we extend our heartfelt appreciation. We are thankful for the collective efforts and support from all those who contributed, directly or indirectly, to the successful completion of our project. Your encouragement has been invaluable, and we truly appreciate the collaborative spirit that made this endeavor possible. A sincere gratitude goes to Dr. Pankaj Raj Dawadi , our project supervisor. His unwavering support, guidance, and constructive feedback have been instrumental in steering our project towards excellence. A special thanks to the Department of Computer Science and Engineering (DoCSE) for providing an enriching academic environment and the necessary resources that played a crucial role in the accomplishment of our team project

Abstract

Hotel operations often became inefficient, and guest experiences were negatively affected because many hotels relied on manual processes or disconnected management systems. This project aimed to develop **Travallee**, a full-stack Hotel Management System that unified core hotel operations on a single digital platform. The system was implemented using a microservices architecture to improve scalability, maintainability, and flexibility. The backend was developed using Node.js, Express, and TypeScript, with Docker used for containerization and scalable database technologies for data management. A responsive web dashboard was built using React and Tailwind CSS to support hotel staff in managing daily operations, while a mobile application developed with React Native and Expo enabled guests to search for hotels, make reservations, and manage bookings conveniently. The completed system provided features such as real-time analytics, room inventory management, centralized guest records, and an efficient reservation process, resulting in improved operational efficiency and an enhanced user experience. In conclusion, Travallee successfully delivered a secure, scalable, and user-friendly hotel management solution. Future enhancements were recommended to include AI-powered guest personalization and predictive analytics for dynamic pricing to further improve hotel operations and customer satisfaction.

Keywords: *Hotel Management System, Microservices, Node.js, React, React Native, Docker*

Chapter 1

Introduction

Travallee is a dual-platform hotel booking and management system developed to connect travelers and hotel owners through a single digital platform. It includes a mobile application where users can search and book hotels according to their needs, and a web-based dashboard that allows hotel owners to manage their listings, update room availability, and track their performance. The system focuses on making the booking process simple for users while also providing useful tools for hotel management. By using modern technologies, it supports real-time updates and smooth interaction between users and hotels, helping to reduce common problems found in existing booking systems.

1.1 Background

The rapid growth of digital technology has changed how people book hotels, with users now relying on mobile applications to search, compare, and reserve accommodations based on their preferences. At the same time, hotels are adopting web-based systems to manage room availability, pricing, and customer interactions, with modern solutions focusing on user-friendly design, real-time updates, and scalable technologies.

However, many existing platforms have limitations. Some focus mainly on user experience while providing limited tools for hotel management, while others are too complex and expensive for small and medium-sized hotels. In many cases, hotels need to use multiple systems for bookings, analytics, and customer management, which increases complexity and reduces efficiency.

These issues highlight the need for a more balanced and integrated system. Travallee addresses this by combining a mobile application for hotel booking with a centralized web dashboard for hotel management, allowing better interaction between users and service providers while improving overall efficiency.

1.2 Objectives

The main objectives achieved during the development of Travallee were:

- Developed a mobile application that enabled users to search, compare, and book hotels efficiently.
- Created a web-based dashboard that allowed hotel owners to manage hotel listings, room inventory, and bookings.
- Implemented features for tracking bookings, revenue, and hotel performance through real-time analytics.

- Ensured secure user authentication and reliable payment transaction handling.

1.3 Motivation and Significance

The rapid growth of digital technology has changed the way people book hotels, as most users now depend on mobile applications to search, compare, and book accommodations based on their needs. At the same time, hotels are also using web-based systems to manage room availability, pricing, and customer details. Recent systems mainly focus on making the interface simple and providing real-time updates using modern technologies.

However, many existing platforms still have some problems. Some systems focus more on users and do not provide enough tools for hotel management, while others are too complex and expensive for small and medium-sized hotels. Also, hotels often need to use different systems for bookings, tracking performance, and managing customers, which makes the process less efficient.

To solve these issues, Travallee provides a combined solution with a mobile app for users to book hotels and a web dashboard for hotel owners to manage their services. This helps to make the system more efficient and easier to use for both users and hotel owners.

Chapter 2

Related Works

The hotel booking industry has evolved significantly with the adoption of digital platforms that enable users to search, compare, and reserve accommodations online. Modern booking systems provide convenient reservation services, secure payment methods, customer reviews, and personalized recommendations. While these platforms have transformed the hospitality industry, many existing solutions either focus on customer-facing services or provide complex management tools designed for large hotel chains. This chapter reviews existing hotel booking platforms related to the proposed Travallee system and identifies the gaps that Travallee aims to address.

2.1 Review of Existing Works

Booking.com

Booking.com is one of the world's leading online travel and hotel reservation platforms. It enables users to search for accommodations, compare prices, read verified customer reviews, and book hotels through web and mobile applications.Booking.com (2026)

- **Technologies/Methodology:** Cloud-based web and mobile platform utilizing advanced search algorithms, secure online booking, customer review systems, and recommendation features.
- **Strengths:** Extensive hotel database, user-friendly interface, secure reservation process, verified customer reviews, and comprehensive filtering options.
- **Limitations:** Primarily focuses on customer booking experience, while hotel management tools are designed for large-scale commercial partners. The platform may be complex for small or independent hotel owners.

While Booking.com provides a comprehensive hotel reservation platform, Travallee focuses on offering a simpler and more accessible solution that combines hotel booking with an easy-to-use management dashboard tailored for small and medium-sized hotels.

Airbnb

Airbnb is a globally recognized online marketplace that connects travelers with hosts offering accommodations, including hotels, apartments, and vacation rentals.Airbnb (2026)

- **Technologies/Methodology:** Web and mobile platform supporting property listings, user authentication, booking management, secure payments, and review-based trust mechanisms.

- **Strengths:** Wide variety of accommodation options, intuitive user interface, trusted review system, and strong community-based platform.
- **Limitations:** Primarily designed for short-term rental hosts and travelers. The management features emphasize property hosting rather than streamlined hotel administration, making it less suitable for traditional hotel operations.

Compared to Airbnb, Travallee focuses specifically on hotel management and reservation services by integrating customer booking with dedicated administrative features for hotel owners in a single platform.

OYO

OYO is a hospitality platform that provides hotel booking services while partnering with hotels to improve operational efficiency and customer experience. OYO Hotels & Homes (2026)

- **Technologies/Methodology:** Integrated hotel management and booking platform supporting online reservations, dynamic pricing, property management, and promotional services.
- **Strengths:** Affordable accommodation options, centralized hotel management, promotional offers, and standardized customer experience.
- **Limitations:** The platform primarily supports hotels operating within the OYO network, limiting flexibility for independent hotel businesses. Many management features are optimized for OYO partners rather than standalone hotel owners.

Unlike OYO, Travallee provides an independent hotel booking and management platform that allows hotels to maintain full control over their operations without being tied to a specific hospitality network.

Figure 2.2: Airbnb Platform

Figure 2.3: OYO Hotel Booking Platform

Chapter 3

Design and Implementation

Travallee is a dual-platform hotel booking and management system developed to connect travelers and hotel owners through a single digital platform. It includes a mobile application where users can search and book hotels according to their needs, and a web-based dashboard that allows hotel owners to manage their listings, update room availability, and track their performance.

3.1 System Overview

Travallee addresses the need for a simple, accessible marketplace by providing a platform where hotel owner can interact directly without the complexity of integrated payments, inventory management. Communication is available immediately through the chat interface.

3.1.1 Major Components:

- **Frontend Development:** TypeScript is used as the programming language. The web dashboard is developed using React.js, while the mobile application is built with React Native. CSS3 and Tailwind CSS are used for styling, and Axios is used as the API client for communicating with the backend.
- **Backend Development:** TypeScript running on Node.js is used for server-side development with the Express.js framework. The backend follows a REST API architecture for client-server communication, and MongoDB is used as the database for storing application data. Redis is used for caching and queue management to improve performance and support asynchronous background task processing.
- **Development Tools:** Visual Studio Code (VS Code) is used as the primary code editor. Git and GitHub are used for version control and source code management. Postman is used for API testing, Expo CLI is used for developing and testing the React Native mobile application, and Docker is used to containerize the application services, ensuring consistent development and deployment across different environments.

3.1.2 Component Interaction

- Guests interact with the React Native mobile application to search hotels, view room details, make reservations, and manage bookings, while hotel owners use the React web dashboard to manage hotels, rooms, bookings, and analytics.

- Both frontend applications communicate with the backend through RESTful APIs over HTTP. The backend processes requests, performs business logic, and returns JSON responses.
- The backend authenticates users using JWT-based authentication and authorizes access based on user roles before performing CRUD operations on the MongoDB database.
- Redis is used for caching frequently accessed data and supporting asynchronous background tasks, improving application performance and reducing response time.
- External services, such as the payment gateway and email notification service, are invoked by the backend to process payments and send booking confirmations or other notifications to users.

3.2 System Requirement Specifications

3.2.1 Software Requirements

Frontend Development

- **Programming Language:** TypeScript
- **Frameworks / Libraries:** React.js (Web Dashboard), React Native (Mobile Application)
- **Styling:** Tailwind CSS
- **API Client:** Axios

Backend Development

- **Programming Language:** TypeScript (Node.js)
- **Framework:** Express.js
- **API Architecture:** Representational State Transfer (REST) API
- **Database:** MongoDB, Redis

Development Tools

- **Code Editor:** Visual Studio Code (VS Code)
- **Version Control:** Git, GitHub
- **API Testing:** Postman
- **Mobile Development Tools:** Expo CLI
- **Operating System:** Windows

3.2.2 Functional Requirements

- Users shall be able to register, log in, and manage their accounts securely.
- Users shall be able to search, view, and book available hotel rooms.
- Hotel owners shall be able to manage hotels, rooms, bookings, and pricing through the web dashboard.
- The system shall process payments and maintain booking records securely.
- The system shall provide real-time room availability and booking updates.
- The system shall generate booking and revenue reports for hotel owners.

3.2.3 Non-Functional Requirements

- The system shall provide a responsive and user-friendly interface across web and mobile platforms.
- The system shall support multiple concurrent users while maintaining consistent performance.
- The system shall ensure secure authentication and protect user data from unauthorized access.
- The system shall be scalable to accommodate future features and increased user demand.

3.3 System Design

3.3.1 Architectural Design

Figure 3.1: System- architecture

3.3.2 Database Design

Travallee uses MongoDB as its primary database to store application data. The database is organized into separate collections for key entities, including **Users, Hotels, Rooms, Bookings Pendingregistrations,chats**. Relationships between collections are maintained using document references, allowing efficient data retrieval while minimizing redundancy. This schema provides the flexibility and scalability required to support hotel management, room reservations, payment processing, and future system enhancements.

3.4 Implementation Details

This section describes how the proposed system architecture was implemented to develop Travallee. The system was developed using a microservices-based client-server architecture consisting of a React web dashboard, a React Native mobile application, and multiple backend services. Each component was implemented independently and integrated through RESTful APIs to provide a seamless hotel booking and management experience.

3.4.1 Frontend Implementation

The frontend consists of a web application developed using React.js, TypeScript, and Tailwind CSS, and a mobile application developed using React Native, TypeScript, and Expo. The web dashboard enables hotel owners and administrators to manage hotels, rooms, bookings, and analytics, while the mobile application allows guests to search hotels, make reservations, complete payments, and manage their bookings. Both applications communicate with the backend through RESTful APIs using Axios, providing synchronized and consistent data across platforms.

3.4.2 Backend Implementation

The backend was developed using Node.js, Express.js, and TypeScript following a microservices architecture. Individual services were implemented to handle authentication, hotel management, room management, booking management, payments, and notifications. JWT-based authentication was used to secure protected API endpoints, while MongoDB was used as the primary database for storing application data. Redis was integrated for caching and background task processing, improving system performance and supporting asynchronous operations such as notifications.

3.4.3 Integration of Components

The frontend applications communicate with the backend through RESTful APIs over HTTPS. The backend services interact with MongoDB for persistent data storage and Redis for caching and queue management. Docker was used to containerize the backend services, ensuring consistent development and deployment across different environments. External services, including the payment gateway and email

notification service, were integrated with the backend to support secure payment processing and automated user notifications. This modular implementation allows the system to remain scalable, maintainable, and easy to extend with additional features in the future.

3.5 Flowcharts

This section presents the flowcharts illustrating the overall workflow and system logic of Travallee. The flowcharts describe the sequence of operations performed by different system components, including user authentication, hotel management, room booking, payment processing, and reservation management. They provide a visual representation of how users, hotel owners, and the backend interact to complete various operations within the system.

Chapter 4

Results and Discussion

4.1 Implemented Features

The hotel booking system successfully implemented several core functionalities:

- **User Authentication:** Users can securely register and log in using JWT-based authentication, ensuring protected access to authorized resources.
- **Hotel Management:** Hotel owners can register their hotels, update hotel information, upload images, and manage hotel profiles through the web dashboard.
- **Room Management:** Hotel owners can add, edit, delete, and manage room details, including pricing, amenities, room images, availability, and occupancy information.
- **Hotel Search and Booking:** Guests can browse hotels, search available rooms, view room details, and make reservations through the mobile application.
- **Payment Integration:** The system integrates digital payment methods to facilitate secure online booking payments.
- **Responsive Web and Mobile Applications:** The system provides a responsive web dashboard for hotel owners and a cross-platform mobile application for guests, ensuring accessibility across multiple devices.

4.2 Results and Performance Analysis

The implemented hotel booking system was tested to evaluate its functionality, performance, and reliability. The testing confirmed that the core features operated correctly and provided a smooth user experience across both the web and mobile applications.

- **Hotel and Room Management:** Hotel owners were able to successfully add, edit, and manage hotel information and room details. All modifications were accurately stored and retrieved from the MongoDB database.
- **Hotel Search and Booking:** Users were able to browse available hotels, view room details, search using basic filters, and complete room reservations successfully. Booking records were correctly maintained in the database.
- **User Authentication:** JWT-based authentication functioned correctly by allowing secure user registration, login, and access to protected resources while preventing unauthorized access.

- **Payment Integration:** The integrated payment gateways processed booking payments successfully, and booking statuses were updated appropriately after payment confirmation.
- **Database Performance:** MongoDB efficiently handled Create, Read, Update, and Delete (CRUD) operations for hotels, rooms, users, and bookings, providing quick response times for common database queries.
- **Cross-platform Functionality:** Both the React.js web application and the React Native mobile application communicated seamlessly with the backend through REST APIs, providing consistent functionality across different platforms.
- **System Stability:** During testing, the system demonstrated stable performance under normal usage conditions. Hotel management, booking operations, user authentication, and database interactions were completed successfully without major errors or system failures.

4.3 Comparison with Objectives or Existing Systems

The implemented hotel booking system successfully achieves its primary objectives by providing an integrated platform for hotel management and room reservation through both web and mobile applications. During the system analysis and design phase, existing hotel booking platforms such as Oyo Rooms, Airbnb, and Booking.com were studied to understand their features, user interfaces, and booking workflows. These platforms served as references for designing an intuitive user experience and identifying essential functionalities expected in a modern hotel booking system. Unlike these commercial platforms, which provide a wide range of advanced services such as global hotel listings, AI-based recommendations, loyalty programs, multilingual support, and extensive third-party integrations, the proposed system focuses on delivering the core functionalities required for efficient hotel management and booking. The implemented system includes secure user authentication, hotel and room management, hotel search, room booking, booking management, and payment integration while maintaining a simple and user-friendly interface.

The system successfully fulfills its intended objectives by offering hotel owners an efficient dashboard to manage hotel operations and providing guests with a convenient platform to browse hotels, view room details, and make reservations. Although it does not yet include all the advanced features available in Oyo Rooms, Airbnb, and Booking.com, the implemented system establishes a scalable foundation that can be extended with additional functionalities such as personalized recommendations, real-time notifications, customer reviews, loyalty programs, and support for multiple payment gateways in future versions.

Some deviations from the original plan:

- **Limited payment gateway support:** Although multiple payment methods were planned, the current implementation supports only the integrated payment gateways, with additional payment options reserved for future development.
- **Recommendation system:** An intelligent hotel recommendation feature based on user preferences and booking history was planned but was not implemented in the current version.
- **Advanced search and filtering:** The system provides basic hotel and room search functionality, while advanced filters such as price range, amenities, ratings, and location-based recommendations are planned for future enhancements.
- **Customer reviews and ratings:** A comprehensive review and rating system with moderation features was planned but only basic review functionality was implemented.
- **Real-time notifications:** Push notifications for booking updates and promotional offers were planned; however, the current system provides only email notifications.
- **Dynamic pricing:** Automatic room pricing based on demand, occupancy, and seasonal trends was proposed but was not implemented in the current version.
- **Hotel comparison feature:** A feature allowing users to compare multiple hotels side by side was planned but remains a future enhancement.

4.4 Discussion

The implementation of the hotel booking system demonstrates the effectiveness of modern web and mobile technologies in developing a unified reservation platform. By integrating a React.js web application, a React Native mobile application, and a Node.js backend with MongoDB, the system provides a consistent and responsive experience across different devices. The use of REST APIs enables seamless communication between the frontend applications and the backend, while JWT-based authentication ensures secure access to protected resources.

The system successfully fulfills its primary objectives by allowing hotel owners to manage hotel information, rooms, and bookings through the web dashboard, while enabling customers to search hotels, view room details, and make reservations using the mobile application. The modular architecture adopted during implementation improves maintainability and allows new features to be integrated with minimal changes to the existing system.

MongoDB's flexible document-based data model efficiently manages relationships among hotels, rooms, users, and bookings, making the system scalable for future ex-

pansion. Although the current implementation satisfies the core functional requirements, additional enhancements such as AI-based hotel recommendations, real-time notifications, advanced analytics, multi-language support, and support for more payment gateways could further improve the usability and overall performance of the system.

Chapter 5

Conclusion and Future Works

The hotel booking system was successfully designed and implemented using modern web and mobile development technologies to provide a seamless booking experience for both hotel owners and guests. The system adopts a client-server architecture, with React.js powering the web application, React Native supporting the mobile application, and Node.js with Express.js handling backend services. MongoDB serves as the primary database, offering a flexible and scalable solution for storing hotel, room, user, and booking information. Secure user authentication is achieved through JWT, while communication between the frontend applications and the backend is facilitated using REST APIs. The implementation provides essential features such as hotel management, room management, booking processing, and user profile management. The responsive web interface and cross-platform mobile application ensure accessibility across different devices. Overall, the proposed system is efficient, reliable, scalable, and user-friendly, providing a solid foundation for future enhancements.

5.1 Limitations

Although the proposed hotel booking system successfully implements the core functionalities required for hotel management and room reservation, it has several limitations that can be addressed in future versions.

- The system supports only the integrated payment gateways, limiting payment options for users.
- The recommendation of hotels is not personalized based on user preferences or booking history.
- The search functionality provides basic filtering and does not support advanced search criteria such as distance-based search or personalized recommendations.
- Internet connectivity is required to access all system features, as the application does not support offline operation.
- The system is designed for small to medium-sized hotels and has not been evaluated under large-scale production workloads.
- Push notifications are not currently supported, and users receive booking updates primarily through email notifications.

5.2 Future Enhancements

Several improvements can be incorporated into future versions of the hotel booking system to enhance its functionality, performance, and user experience.

- Integrate additional payment gateways to provide users with more payment options.
- Implement an AI-based hotel recommendation system using user preferences and booking history.
- Enhance the search functionality with advanced filters, location-based search, and personalized recommendations.
- Introduce push notifications for booking confirmations, cancellations, promotional offers, and reminders.
- Add multilingual support to improve accessibility for users from different regions.
- Develop a loyalty and rewards program to encourage repeat bookings.
- Implement dynamic room pricing based on demand, occupancy, and seasonal trends.
- Expand the analytics dashboard with predictive insights and business intelligence reports for hotel owners.
- Integrate third-party map and navigation services to improve hotel discovery and route guidance.
- Enhance system scalability by adopting container orchestration platforms such as Kubernetes for large-scale deployments.
